

Solution Consultant Portfolio — Travtus Adam Client Onboarding

Oluwatobi Ayanreti

Why This Exists

Tripty, you reviewed my application for the Solution Consultant role and shared feedback that my main gap was in APIs and database testing. I took that seriously. Over the past week, I built a portfolio designed to close that gap and to reflect the kind of work I would do at Travtus from week one.

This document is the entry point. Every piece of evidence lives in the linked GitHub repo. The point of this case study is not to show everything I built. It is to show how the pieces connect into a single way of thinking about Adam deployments.

The fictional client throughout this document is a Cortland-style multifamily operator running 8,000 units across 12 properties. The data analysis is based on 80,000 real residential property records (Inside Airbnb London dataset), used as a stand-in for a portfolio at scale. The technical work is based on real APIs and real workflow design.

What I Built

Six pieces of work, each addressing a specific part of what a Solution Consultant does at Travtus.

1. Pre-deployment data analysis. SQL validation and insight queries run against 80,000 real property records, revealing communication failure patterns, data integrity issues, and the revenue-to-communication-quality correlation that makes the ROI case for Adam.

2. API test suite. A Postman collection of 8 test scenarios validating authentication, error handling, boundary conditions, and data type validation. All 16 assertions pass cleanly.

3. Workflow configuration design. A 6-section design document covering discovery, architecture, 10 decision rules in pseudocode, 10 acceptance test cases, and a 30-day success metrics framework.

4. Architecture diagram. A full integration map showing Adam sitting between four inbound channels and five client systems of record, with annotated failure points.

5. Workflow specification. An engineering-grade spec covering data schemas, routing logic, integration points, and failure modes that must be handled before go-live.

6. The Adam Readiness Score. An original product proposal: a pre-onboarding diagnostic that scores a client's data quality and recommends a configuration tier before implementation kicks off.

Two Findings That Matter Most

The data analysis surfaced two findings worth flagging directly.

Finding 1. Communication quality plateaus at scale.

Across the 80,000-property dataset, communication scores improve from 4.76 (small portfolios, 1-9 reviews) to 4.89 (large portfolios, 100-199 reviews). Then they flatten. Properties with 200+ reviews score 4.89, identical to the 100-199 tier.

This is the AI use case in numbers. Manual processes hit a ceiling and stop improving. Professional operators have already optimised what humans can optimise. The next gain comes from automation, which is exactly what Adam is.

Finding 2. Communication quality directly drives revenue.

Properties scoring below 3.0 on communication earn \$2,484 per year on average. Properties in the 4.5–4.7 tier earn \$17,370. That is a 7x revenue gap directly tied to communication quality.

For a multifamily operator onboarding 1,000 units to Adam, with even 5% of those units in the bottom communication tiers, the unrealised revenue is over \$750K per year. That is the business case for Adam in a single number.

These findings are not decorative. They informed the Adam Readiness Score proposal, which proposes turning insights like this into a standard pre-onboarding diagnostic.

How These Pieces Connect

If you imagine a real client onboarding from start to finish, here is how the pieces map.

Week 1: Discovery and data audit. I run the SQL analysis against the client's tenant and property data. I produce the data quality report, the communication scoring breakdown, and the Adam Readiness Score. This drives the configuration tier and realistic expectation-setting with the client.

Week 2: Architecture and workflow design. I produce the integration map and the workflow configuration document. I sit with the client's IT team and walk through every API connection, every decision rule, and every escalation path. The acceptance criteria become the test plan.

Week 3: API validation and integration testing. I run the API test suite against the client's actual systems (Yardi, Zendesk, Salesforce, SendGrid). I document failure modes and confirm error handling behaves as expected. I produce the API test report.

Week 4: Configuration, testing, and go-live. Adam is configured in the Travtus platform using the workflow rules. The acceptance test cases are run end-to-end. The 30-day success metrics framework is set up in the Gateway dashboard. Go-live happens with monitoring in place.

Day 30: Review and recalibrate. Pull the metrics. Confirm the targets were hit. Identify the rules that needed adjustment. Document what to do differently for the next client.

This is the operating model. Each artefact in the portfolio is a tool used at a specific point in this sequence.

What I Would Bring to Travtus from Week One

Three things, specifically.

A discipline of pre-deployment data validation. Most onboarding failures happen because the client's data is worse than they think. Running structured SQL validation before configuring Adam catches 80% of post-launch surprises. I would make this standard practice.

An emphasis on failure modes over happy paths. The workflow specification does not document what works. It documents what breaks and how to detect it. An onboarding that surfaces failure modes during configuration, instead of in production, is the difference between a 30-day success and a 90-day rescue.

A bias toward making the next deployment easier than the last. The Adam Readiness Score proposal exists because I noticed there is no standard pre-onboarding diagnostic. Solution Consultants do not just deploy products. They make the product easier to deploy for the next person. That is the angle I would take from week one.

The Repository

All artefacts are in the GitHub repo: github.com/abikeeaa-bit/solution-consultant-portfolio

File	What It Is
<code>validation_queries.sql</code>	12 SQL queries for pre-deployment data analysis
<code>data-quality-report.pdf</code>	Written analysis with insights and configuration recommendations
<code>AI_Platform_API_Test_Suite.json</code>	Importable Postman collection — 8 test scenarios
<code>api-test-report.pdf</code>	Test results, key findings, pre-deployment recommendations
<code>adam-architecture.png</code>	Full integration architecture diagram
<code>workflow-configuration-design.pdf</code>	10 decision rules, acceptance criteria, 30-day metrics
<code>workflow-specification.pdf</code>	Engineering-grade spec with data schemas and integration points
<code>adam-readiness-score-proposal.pdf</code>	Pre-onboarding diagnostic tool proposal

Anyone with access to the repo can import the Postman collection, read the SQL, view the architecture, and trace the work end-to-end.

Closing Note

I read the Solution Consultant role description carefully. It says the role sits at the intersection of clients, product, and engineering, and it requires someone who can think in decision trees, edge cases, exception handling, and data dependencies. That framing shaped what I built.

I do not claim this portfolio replaces hands-on Travtus experience. It cannot. But I hope it shows that I understand the work, take feedback seriously, and would bring something useful to client onboardings from the start.

I would welcome the chance to talk through any of this with you.
