

Adam Readiness Score: A Pre-Onboarding Diagnostic Proposal

Author: Oluwatobi Ayanreti

The Problem

Every Travtus client onboarding starts from scratch. The Solution Consultant arrives, runs discovery, reviews the client's data, and forms a judgement about how broken the current communication setup is. That judgement then drives configuration decisions for Adam, the implementation timeline, and the expectations set with the client.

That judgement, however, is made informally. There is no standard scorecard. Two SCs looking at the same client could reasonably reach different conclusions about how aggressive Adam's escalation rules should be, how long onboarding will take, or how realistic a 30-day improvement target is.

This creates three problems. Configuration decisions become inconsistent across deployments, which makes it harder to learn what actually works. Clients with bad data get treated the same as clients with clean data until problems surface mid-deployment. And there is no easy way to show a prospect what their starting point looks like before they sign.

The Proposal

Build a lightweight diagnostic tool called the **Adam Readiness Score**. It runs against a client's existing communication and resident data before onboarding begins, takes about two hours of SC time per client, and outputs a single number from 0 to 100, plus a recommended configuration tier.

The score gives the SC a quick, defensible read on what they're walking into. It gives the client a clear picture of where they stand today. And over time, it gives Travtus a dataset of starting points that can be correlated with deployment outcomes, so we can learn which configurations work for which client profiles.

How It Would Work

The score is built from five inputs, all pulled from the client's existing data during the discovery phase.

Input	What It Measures	Weight
Average response time	How fast the operator currently replies to residents across all channels	25%
Communication score (resident survey)	How residents rate the operator on communication today	25%
% missing contact data	The portion of residents with no email or phone on file	20%
% stale records	Residents who haven't been contacted or active in over 12 months	15%
Complaint recurrence rate	The portion of issues escalated more than twice in 30 days	15%

Each input is normalised to a 0-100 scale, weighted, and summed into a final score.

Output: Three Configuration Tiers

The score maps directly to a recommended configuration tier for the deployment.

Standard (Score 70-100). The client's data is clean, response times are reasonable, and residents are reachable. Adam can be deployed with default escalation thresholds and a typical 4-week onboarding. Expected 30-day improvement is moderate but consistent.

Accelerated (Score 40-69). The client has meaningful gaps. Some data cleanup is needed before go-live. Escalation thresholds should be set more aggressively than default to compensate for backlogs. The SC should plan for a 6-week onboarding with one extra check-in at week 3. Expected 30-day improvement is significant.

Intensive (Score 0-39). The client's communication infrastructure is in critical condition. Major data remediation is required before Adam can be safely deployed. The SC should plan for an 8-week onboarding, weekly check-ins, and a phased rollout starting with the highest-risk properties. Expected 30-day improvement is dramatic but requires careful expectation-setting with the client to avoid overpromising.

Why This Is Worth Building

It's defensible. Every onboarding decision has a number behind it instead of "in my judgement, this client needs more time."

It's a sales asset. The Readiness Score can be shown to a prospect during the discovery call. It turns a vague conversation about "we need to improve communication" into a concrete diagnostic the prospect wants to see resolved. That's a closing tool.

It compounds. Every onboarding adds a data point. Over time, Trvtus builds a benchmark dataset showing which scores correlate with which deployment outcomes. That feeds back into the configuration logic, and the next generation of SCs makes better calls than the last.

It costs almost nothing to build. The inputs are already pulled during discovery. Wrapping them in a scoring formula and a recommendation engine is one engineer-week of work, plus a simple UI inside the Trvtus Gateway.

How I Came To This

I built this proposal after running an analysis on 80,000 real residential property records (the Inside Airbnb London dataset, used as a stand-in for a multifamily portfolio at scale). Two findings drove the idea.

First, communication scores plateau at the top end of the portfolio size scale. Properties with 100+ reviews score 4.888, and properties with 200+ reviews score 4.886. Manual processes hit a ceiling and stop improving. This is the AI use case in numbers.

Second, properties in the bottom communication tier (below 3.0) earn \$2,484 per year. Properties in the "Good" tier (4.5-4.7) earn \$17,370. That's a 7x revenue gap directly tied to communication quality. For a client onboarding 1,000 units with even 5% in the bottom tiers, that's \$750K of unrealised annual revenue.

Both findings point to the same conclusion: the gap between a high-performing client and a low-performing one is enormous, and Trvtus needs a way to quantify that gap before onboarding starts. The Readiness Score is the simplest version of that tool.

What I'd Want to Hear From the Trvtus Team

I don't know if something like this exists internally already. If it does, I'd love to learn how it's used. If it doesn't, I'd want to understand whether the framing fits

how Travtus thinks about onboarding, and whether the inputs I've chosen are the right ones for a multifamily context (versus the Airbnb proxy data I worked with).

Either way, this is the kind of work I'd want to bring to the role. Solution Consultants don't just deploy products; they make the product easier to deploy for the next person. That's the angle I'd be looking to take from week one.
